Chapter 1

Introduction

This reference manual provides a detailed description of the Bluetooth® Low Energy (BLE) Host Stack serial commands, communication packet structure, and usage of the Framework Serial Communication Interface (FSCI).

1.1 Scope and objective

This document describes the BLE Host Stack functionality through a serial communication interface to a host system. The typical serial interfaces are UART, SPI, and I2C. The typical applications employing the BLE Host Stack FSCI functionality can be desktop applications, such as the NXP Test Tool for Connectivity Products, or embedded systems that have a Bluetooth® LE applications which use BLE stack services via FSCI.

1.2 Audience description

This reference manual is intended for profile/application designers and users of the BLE Host Stack FSCI.

Chapter 2

Overview

The FSCI (Framework Serial Communication Interface) module supports interfacing the BLE Host Stack with a host or a PC tool (TestTool for Connectivity Products) using a serial communication line. If the FSCI is used with the NXP Test Tool for Connectivity products, this tool can use an XML file which contains a detailed meta-description for serial commands and events. This XML file is provided in software packages which include this document.

2.1 BLE Host Stack interface set

The BLE Host Stack layers that offer access using FSCI are GATT, GATTDB, L2CAP CB, and GAP. Each layer provides primitives that an upper layer (profile/application) uses to access services of that layer. This document includes a detailed list of the provided primitives.

2.2 Basic requirements

- IAR Embedded Workbench for ARM® architecture
- NXP development boards (to be loaded with the “ble_fsci_app” application)
- Optional BLE sniffer for testing • PC tool (TestTool for Connectivity Products) or another host processor capable of communicating through UART, USB, SPI, or I²C

2.2.1 Interface description

The FSCI module uses the Serial Manager and needs one of the following interfaces for communication:

- A 2-wire UART connection
- A 3-wire I²C connection
- A 5-wire SPI connection
- A USB connection

2.3 Overview and packet structure

The FSCI module sends and receives messages as shown in the figure below. This structure is not specific to a serial interface and is designed to offer the best communication reliability. The device is expecting messages in little-endian format and responds with messages in little-endian format.

Figure 1. Packet Structure

Table 3. Packet Field Description

Field Name	Length (bytes)	Description
STX	1	Used for synchronization over the serial interface. The value is always 0x02.
Opcode Group	1	Distinguishes between different layers (for example, GAP, GATT, and GATTDB).
Message Type	1	Specifies the exact message opcode that is contained in the packet.
Length	2	The length of the packet payload, excluding the header and the checksum. The length field content shall be provided in little endian format.
Payload	variable	Payload of the actual message.
Checksum	1	Checksum field used to check the data integrity of the packet.

Chapter 3

FSCI Messages Description

This chapter describes all L2CAP CB, GAP, GATT, and GATTDB commands (requests) and events (confirms and indications) in detail. The “BLE.xml” document found in the ble_fsci_app subfolder provides an XML representation of all these commands and events.
